Ask the Historian

Faraday’s Laws or Faraday’s Law?

William B. Jensen

Department of Chemistry, University of Cincinnati
Cincinnati, OH 45221-0172

Question

I have noticed that some textbooks refer to Faraday’s laws of electrolysis whereas others refer just to Faraday’s law. Which is correct and why?

James Bohning
Department of Chemistry
Lehigh University
Bethlehem, PA 18015

Answer

In sharp contrast to the approach taken in earlier columns, this question is best answered mathematically, rather than historically, by first providing a rigorous derivation of Faraday’s law(s) using the notational system introduced by the Belgian physicist, Théophile De Donder, (1872-1957), in the 1920s (1). Thus, for a generalized chemical reaction:

\[ aA + bB \rightarrow cC + dD \]  \[ \text{[1]} \]

the change in the amount or extent of reaction, \( d\xi \), measured in units of moles of reaction events, is defined as the change in the moles, \( dn_s \), of any of the various species, \( s \), in the reaction, weighted by its stoichiometric coefficient, \( \nu_s \), in the balanced equation:

\[ d\xi = dn_s/\nu_s \]

where \( \nu_s \) is assumed to have the units of moles of species \( s \) per mole of reaction and to be inherently negative for reactants and inherently positive for products. Using these conventions, De Donder was also able to express the rate of a reaction in terms of the change in its extent of reaction per unit time (2):

\[ d\xi/dt = (dn_s/dt)/\nu_s \]

Applying this notation to the equation for a typical electrochemical reduction:

\[ \nu_0 \text{Ox} + \nu_e \text{e}^- \rightarrow \nu_1 \text{Red} \]  \[ \text{[4]} \]

we can express its rate of reaction, \( d\xi/dt \), in terms of either the weighted change in the moles of electrons consumed per unit time, \( (dn_e/dt)/\nu_e \), or the weighted change in the moles of any one of the various chemical species generated or consumed per unit time \( (dn_s/dt)/\nu_s \):

\[ (dn_e/dt)/\nu_e = (dn_s/dt)/\nu_s \]  \[ \text{[5]} \]

Multiplying both sides of this equation by Faraday’s constant, \( F \), having the units of coulombs per mole electrons, and using the fact that the product, \( Fdn_e \), is equal to the change in the number of coulombs, \( dQ \), and its time derivative, \( dQ/dt \), is, in turn, equal to the electric current, \( i \), gives us:

\[ F(dn_e/dt)/\nu_e = (dQ/dt)/\nu_e = i/\nu_e = F(dn_s/dt)/\nu_s \]  \[ \text{[6]} \]

Regrouping the terms and defining the ratio \( (\nu_e/\nu_s) \) as \( z_s \), with the units of moles of electrons per mole of species \( s \), we obtain the differential form of Faraday’s law:
In an introductory chemistry course we usually further assume that the current, \( i \), is constant over time, thus allowing us to use a simple integrated form of equation 7 instead:

\[
idt = \left(\frac{\nu_e}{\nu_i}\right)Fdn_s = z_sFdn_s \quad [7]
\]

Regrouping the terms again and recognizing that \( MW_s/z_s \) for a given species, \( s \) is equal to its electrochemical equivalent weight, \( EW_s \), we obtain, provided that \( Q \) is kept constant, the mathematical equivalent of Faraday’s second law:

\[
m_s = Q/F(MW_s/z_s) \quad \text{or} \quad m_s = k'(EW_s)Q \quad [11]
\]

Based on these derivations, we can draw a number of important conclusions:

1. Since the two traditional verbal laws can be combined into a single mathematical equation (equation 8), it is more appropriate to talk of Faraday’s law rather than Faraday’s laws (5).

2. As demonstrated by the Italian chemist, Carlo Matteucci (1811-1868), in 1839, the relationship embodied in equation 8 is equally applicable to both an electrolysis cell and to a voltaic cell (in which case it correlates the current generated by the cell with the amount of reaction within the cell, rather than the amount reaction in the cell with the applied current) (6). Hence, it is no longer appropriate to talk of Faraday’s law of electrolysis. Rather it should be called, following Faraday’s original suggestion, Faraday’s law of electrochemical action, in which the concluding qualifier is necessary in order to distinguish it from “Faraday’s law of magnetic induction,” as used in the field of electromagnetism.

3. Our derivation clearly shows that, in contrast to the Nernst equation, which is thermodynamic in nature, Faraday’s law of electrochemical action is kinetic in nature (7).

Though I was taught equation 8 as an undergraduate, I was rather surprised to recently discover that the author of the Freshman textbook used at Cincinnati seems to be unaware of it and that the entire subject is essentially missing from the textbook currently being used in our undergraduate physical chemistry course. A quick review of additional Freshman and physical chemistry textbooks yielded similar results. In many cases only the verbal equivalent of the first law was given or a series of special-case relationships similar to equations 10 and 11, thus suggesting that it is time that we finally update our textbook coverage of this subject.
Literature Cited

2. For homogeneous reactions, the reaction rate is usually expressed as the rate per unit volume, $dξ/Vdt$, whereas for heterogeneous reactions, it is usually expressed as the rate per unit area, $dξ/Adt$. If Faraday’s law is derived using the latter, rather than just the simple rate, then it must be restated in terms of current densities, $i/A$, which is not normally done in an introductory course.

5. An earlier attempt to reduce Faraday’s laws to a single equation, in which several of the variables in equation 8 are implicit, rather than explicit, may be found in F. C. Strong, “Faraday’s Laws in One Equation,” *J. Chem. Educ.*, 1961, 38, 98.
